New edition:

Koyo MINIATURE AND EXTRA-SMALL BALL BEARINGS CATALOG

Preface

Thank you for your valuable support of JTEKT products.

Recent industrial applications demand more sophistication in a variety of machines and equipment with the improvement of environment-protection policy.

Rotation parts for information processing, audio, and visual equipment that include such features as high tolerance and low torque are highly desired by users.

To meet such demands, we at JTEKT exploit state-of-the-art research facilities and leading-edge production methods to improve the performance and life of tolerance miniature and extra-small ball bearings.

The information contained in this catalog is the result of our research activities. We believe that this catalog will aid users in the selection and utilization of miniature and extra-small ball bearings.

Through our efforts in research and technical development, and by obtaining inspiration from the marketplace, JTEKT can continually offer the best technologies, quality, and services.

We trust that you will be as satisfied with our latest products and services as you have been in the past.

★The contents of this catalog are subject to change without prior notice. Every possible effort has been made to ensure that the data herein is correct; however, JTEKT cannot assume responsibility for any errors or omissions.

Bearing Technical Section

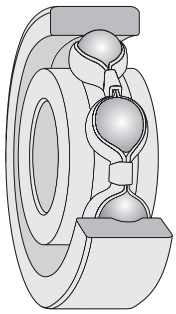
1. Bearing Types and Features

Miniature and extra-small ball bearings include those with outer ring flanges, thin section types, and narrow-width types, as well as standard ones. The above are also categorized as open, shielded, and sealed types.

The miniature and extra-small ball bearings in this catalogue are deep groove ball bearings.

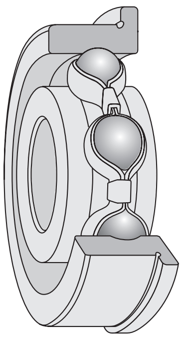
1.1 Types and Features

1) Open types



This type of bearing can carry a radial load and axial load in both directions simultaneously. Featuring low frictional torque, it is suitable for applications where high rotation speed or low noise and vibration are required.

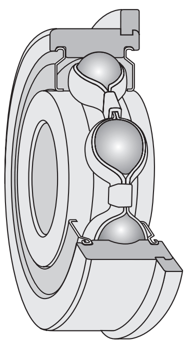
2) Outer ring flange types



This type of miniature and extra-small ball bearings has a flange on one end of the outside surface.

Since mounting is carried out using the side of the housing as reference, this type of bearing simplifies installation by easily positioning itself in the axial direction.

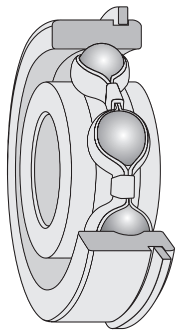
3) Outer ring resin flange types (FN bearings)



In this type of bearing a resin flange is injection molded around the outside surface, as an alternative to the solid outer ring flange.

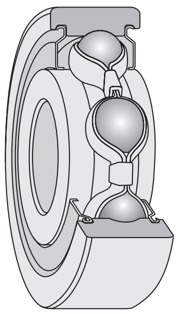
This newly developed item is approximately 10% lighter than a conventional miniature and extra-small ball bearings with an outer ring flange.

4) Locating snap ring types



With this type of bearing, mounting in a housing is simple, as its positioning in the axial direction is carried out using a locating snap ring.

5) Shielded and sealed types



These types of miniature and extra-small ball bearings are sealed by shields or rubber seals to prevent leakage of lubricating grease or entry of foreign matter.

Since the appropriate quantity of a high quality lubricating grease is factory sealed, the sealed miniature and extra-small ball bearings allows simplification of sealing devices around the bearing and facilitates easy handling.

Shielded and sealed miniature and extra-small ball bearings with outer ring flange are also available.

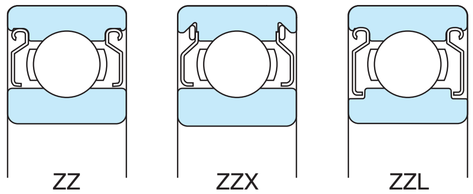
Types, structures and features of shielded and sealed miniature and extra-small ball bearings

(1) Shielded types ZZ(Z), ZZX(ZX), ZZL(ZL)

In this type of bearing, a press-worked shield is utilized.

These bearings are classified as Z and ZX types according to the manner in which the shield is fixed to the outer ring. A ZL type, in which the inner ring is provided with a groove, is also available.

A carbon steel or stainless steel plate is used for the shield.



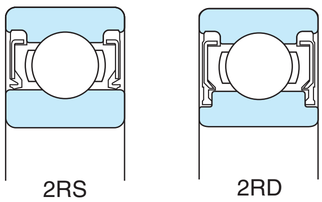
(ZZ, ZZX, ZZL···dual-shielded type
Z, ZX, ZL···single-shielded type)

(2) Contact sealed types 2RS(RS), 2RD(RD)

A contact rubber seal is included on this type of sealed deep groove ball bearing.

This type of bearing offers excellent grease sealability and dust prevention as its structure is such that the seal lip is in contact with either the shoulder of the inner ring (outside surface of inner ring) or with the shoulder step.

These bearings come in standard RS type and low frictional torque RD type.



(2RS, 2RD···dual-sealed type
RS, RD···single-sealed type)

<Features of the RD seal>

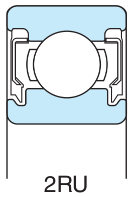
The RD seal has a labyrinth structure in the shape of a letter Z formed by the seal lip and inner ring seal groove. The torque requirement of this type of bearing is as low as that of the non-contact type since the lip is extremely light contact with the seal groove of the inner ring, yet this newly developed item offers excellent grease sealability and dust prevention.

(3) Non-contact sealed types 2RU(RU)

This type of sealed deep groove ball bearing utilizes a rubber or resin non-contact seal.

Since the labyrinth is formed between the seal lip and the seal groove step in the inner ring, it is superior in grease sealability and dust prevention.

Being a non-contact type, it is suitable for high-speed applications with low frictional torque requirements.



(2RU···dual-sealed type
RU···single-sealed type)

1.2 Designation Structure

The designation of a bearing indicates the specifications of the bearing, such as bearing type, boundary dimensions, dimension accuracy, running accuracy, and internal clearance. It consists of a basic number and a supplementary code.

Designation of standard bearings conforming to JIS B 1512 (Boundary Dimensions for Rolling Bearings) is specified by JIS B 1513.

In addition to JIS designation, JTEKT uses supplementary codes, for ease of understanding of bearing specifications.

The designation structure is shown in Tables 1.2 to 1.3.

1.3 Cages

In general, a ribbon type or crown type cage made of steel is used in miniature and extra-small ball bearings. The ribbon type cage is used in relatively large bearings, while the crown type is used in smaller ones.

Molded polyamide resin cages are becoming increasingly popular, as they are advantageous in terms of frictional torque, grease life, and noise.

Table 1.4 shows types, codes, and names of cages used in miniature and extra-small ball bearings.

2. Bearing Life and Load Rating

2.1 Bearing Life

When a bearing rotates under a load, the raceway surfaces of the inner and outer rings and the rolling contact surfaces of the rolling elements are constantly subjected to alternating load. Even under proper operating conditions this results in scale-like damage (known as peeling or flaking) on the surfaces of the race-way or surfaces of the rolling elements due to material fatigue.

The total number of rotations reached prior to this damage is known as "the (fatigue) life" of a bearing.

Substantial variations in (fatigue) life occur even if bearings of the same structure, dimensions, materials, machining method, etc. are operated under identical conditions. This is due to the discreteness in fatigue life, an intrinsic phenomenon to the material, which shall be studied in terms of statistics.

The total number of rotations at which 90% of the same bearings operated individually under the same conditions should be free of damage caused by rolling fatigue (in other words, bearing life of 90% reliability), is referred to as "the basic rating life."

If bearings are operated at a constant rate, the basic rating life is expressed in total running hours.

In miniature and extra-small ball bearings, it is rare that fatigue life becomes an issue of concern. Factors affecting the service life of such bearings are the decline of bearing performance and deterioration of lubricant, which appear before flaking occurs.

Specifically, bearings used for audio and office automation equipment and aircraft instruments are required to offer a high level of noise, vibration, and frictional torque performance. Practical bearing life ends when a bearing becomes incapable of meeting its performance requirements.

2.2 Calculation of Bearing Service Life

2.2.1 Basic Dynamic Load Rating

The strength of a bearing against rolling fatigue (C) – that is, the basic dynamic load rating representing the load-bearing capacity – is the net constant radial load (in the case of a radial bearing) that a bearing, with either the inner/outer ring stationary and the other rotating, can endure for a rating life of 1 million rotations.

The basic dynamic load rating of a radial bearing is also known as "the basic dynamic radial load rating (C_r)." Its values are given in the bearing dimension tables.

2.2.2 Basic Rating Life

The relationship among the basic rating life, the basic dynamic load rating, and the dynamic equivalent load is expressed by Equation (2.1).

If a bearing is to be operated at a constant rotation speed, its life is conveniently expressed in hours as shown in Equation (2.2).

Total number of rotations $$L_{10} = \left(\frac{C}{P}\right)^p \quad \cdots\cdots (2.1)$$

Hours $$L_{10h} = \frac{10^6}{60n}\left(\frac{C}{P}\right)^p \quad \cdots\cdots (2.2)$$

where,

L_{10} : basic rating life, 10^6 rotations

L_{10h} : basic rating life, h

P : dynamic equivalent load, N ····· (See 2.3 on Page 9)

C : basic dynamic load rating, N

p : exponent, for ball bearings ········ $p = 3$

(for roller bearings ······ $p = 10/3$)

n : rotation speed, min^{-1}

When a bearing is operated under a dynamic equivalent load P and rotation speed n, the basic dynamic load rating C of the bearing, which is adequate for meeting the design life, is given by Equation (2.3). Thus, the dimensions of the bearing are determined by selecting a bearing from the bearing dimension tables, which meets the required dynamic load rating C_r.

$$C = P\left(L_{10h} \times \frac{60n}{10^6}\right)^{1/p} \quad \cdots\cdots (2.3)$$

Reference

The formula below is derived from Equation (2.2) by applying a life coefficient (f_h) and speed coefficient (f_n).

$$L_{10h} = 500\, f_h^{\,3} \quad \cdots\cdots (2.4)$$

Life coefficient : $$f_h = f_n \frac{C}{P} \quad \cdots\cdots (2.5)$$

Speed coefficient : $$f_n = \left(\frac{10^6}{500 \times 60n}\right)^{1/3} = (0.03n)^{-1/3} \quad \cdots\cdots (2.6)$$

Values of f_n, f_h, and L_{10h} are determined approximately by nomograms as shown in Fig. 2.1.

2.2.3 Temperature Corrections for Basic Dynamic Load Ratings and Dimension Stabilizing Treatment for Bearings

When bearings are operated at high temperatures, their material structure changes, and thus their hardness decreases as well as the basic dynamic load rating lowers by use at normal temperature.

Once the material structure has changed, it does not recover even if the temperature returns to normal.

Accordingly, the basic dynamic load ratings indicated in the bearing dimension tables must be corrected by multiplying by a temperature coefficient shown in Table 2.1 when used at high temperature.

Table 2.1 Temperature Coefficient Values

Bearing Temperature, °C	125	150	175	200	250
Temperature Coefficient	1	1	0.95	0.9	0.75

When a bearing which has only undergone ordinary heat treatment is operated at 120 °C or higher for an extended period of time, a substantial dimensional change occurs. Thus it needs dimension stabilizing treatment.

The codes and operating temperature ranges for dimension stabilizing treatment are shown in Table 2.2.

The hardness of such bearings, however, is low, so in some cases their basic dynamic load ratings may decrease.

Table 2.2 Bearing Dimension Stabilizing Treatment

Dimension Stabilizing Treatment Code	Operating Temperature Range
S0	> 100 °C, ≦ 150 °C
S1	> 150 °C, ≦ 200 °C
S2	> 200 °C, ≦ 250 °C

2.2.4 Corrected Rating Life

The basic rating life (L_{10}) expressed by Equation (2.1) is the (fatigue) life with 90% reliability. The reliability should be higher than 90% for some applications. Bearing life may be extended by adopting specific materials. In addition, operating conditions such as lubrication may affect bearing life.

The basic rating life taking these conditions into consideration is known as the corrected rating life, which is determined by Equation (2.7).

$$L_{na} = a_1 a_2 a_3 L_{10} \quad \cdots\cdots (2.7)$$

where,

L_{na} : corrected rating life, 10^6 rotations
(Bearing life at 100−n% reliability-namely, breakage probability n%-considering bearing characteristics and operating conditions)

L_{10} : basic rating life, 10^6 rotations (90% reliability)

a_1 : reliability coefficient ························ See (1)

a_2 : bearing characteristic coefficient ····· See (2)

a_3 : operating condition coefficient ········· See (3)

[Note] When selecting bearing using an L_{na} with a reliability exceeding 90%, special consideration should be given to the strength of the shaft and housing.

(1) Reliability Coefficient, a_1

Table 2.3 shows a_1 values used to determine the corrected rating life at reliabilities of 90% or higher (10% or less for breakage probability).

Table 2.3 Reliability Coefficient, a_1

Reliability, %	L_{na}	a_1
90	L_{10a}	1
95	L_{5a}	0.62
96	L_{4a}	0.53
97	L_{3a}	0.44
98	L_{2a}	0.33
99	L_{1a}	0.21

(2) Bearing characteristic coefficient, a_2

The bearing characteristic variables pertaining to service life may changes because of different bearing material (steel type and quality), manufacturing process, and design. a_2 is used for correction in such cases.

JTEKT applies high-quality vacuum degassed bearing steels as standard bearing material. The results of our tests show it to have substantial extended bearing life. The basic load ratings indicated in the bearing dimension table are based on bearings of this material. In such cases, assume a_2=1.

Additionally, for bearings using a specific material aimed at extending fatigue life, the value of a_2 can be greater than 1.

(3) Operating conditions coefficient, a_3

a_3 is used for correction where a bearing operating condition has a direct influence on bearing life (especially, the adequacy of lubrication).

When lubrication is normal, a_3=1. a_3 can be greater than 1 if the lubrication is especially good.

$a_3 < 1$ under the conditions below.

- Lubricant during operation has low kinematic viscosity
  Ball bearings ·········· $\leqq$ 13 mm^2/s
  (Roller bearings ······ $\leqq$ 20 mm^2/s)
- Use at a very low rotation speed,
  where the product of pitch diameter of rolling element and rotation speed $\leqq$ 10 000
- Foreign matter enters lubricant
- Inner and outer rings incline considerably

[Note]
If the hardness of a bearing decreases during operation at high temperatures, a correction to the basic dynamic load rating is required (see Table 2.1 on Page 8)
[Remark]
$a_2 \times a_3$ may not be greater than 1 when lubrication is inadequate, even if $a_2 > 1$ owing to the use of a specific material.
Consequently, in general, $a_2 \leqq 1$ if $a_3 < 1$.
Since it is not easy to view a_2 and a_3 as independent coefficients, they are treated in some cases as a single coefficient, a_{23}.

2.3 Dynamic Equivalent Load

Bearings are often subjected to a resultant load consisting of radial and axial loads, with their various load conditions and magnitudes being variable.

Thus it is impossible to compare the actual load of a bearing with the basic dynamic load rating.

Then, a method in which the actual load is conversed to a virtual load of a constant magnitude and direction applied to the bearing center is applied. Under such virtual load, the bearing life is equal to that resultant from an actual load and rotation speed. This calculated virtual load is called the dynamic equivalent load (P).

The dynamic equivalent load of a radial bearing receiving a resultant load constant in magnitude and direction is obtained by Equation (2.8).

$$P_r = XF_r + YF_a \quad \cdots\cdots (2.8)$$

where,
P_r : dynamic equivalent radial load, N
F_r : radial load, N
F_a : axial load, N
C_{0r} : basic static radial load rating, N
······ (See 2.4 on Page 10)

[Notes] 1) Coefficient f_0 is shown in the bearing dimension table.
2) i means the number of rows of rolling elements in a bearing.

2.4 Basic Static Load Rating and Static Equivalent Load

2.4.1 Basic Static Load Rating

Under an excessive static load or with an impact load at very low rotation speed, bearings can experience local permanent deformation of the contact surfaces between the rolling elements and raceways. The magnitude of this permanent deformation increases as the load becomes greater. This will eventually impair the bearings ability to operate smoothly.

The basic static load rating (C_0) refers to the static load corresponding to the following calculated contact stress, which is working at the center of contact between the rolling element and raceway where the maximum load is applied.

- Deep groove ball bearings .... 4,200 MPa
  (including miniature and extra-small ball bearings)
- Self-aligning ball bearings .... 4,600 MPa
- Roller bearings .... 4,000 MPa

The total permanent deformation of the rolling element and raceway occurring under such contact stress as indicated above is approximately 0.0001 times the diameter of the rolling element.

The static load rating of radial bearings is known as the basic static radial load rating (C_{0r}). Its values are shown in the bearing dimension tables.

2.4.2 Static Equivalent Load

The static equivalent load (P_0) refers to a calculated virtual load. The magnitude of this load is determined through conversion, such that the load would produce a contact stress equal to that produced under actual loading conditions, occurring at the center of contact between the rolling element and raceway under the virtual load while the bearing is at rest or rotating at a very low rate.

For radial bearings, the radial load working at the bearing center is employed, which is referred to as the static equivalent radial load (P_{0r}).

The static equivalent load is obtained by Equations (2.9) and (2.10).

[Radial bearing] ······The larger of the values determined by the following two equations is adopted.

$$P_{0r} = X_0 F_r + Y_0 F_a \quad \cdots\cdots (2.9)$$

$$P_{0r} = F_r \quad \cdots\cdots (2.10)$$

where,

P_{0r} : static equivalent radial load, N
F_r : radial load, N
F_a : axial load, N
X_0 : static radial load factor (0.6)
Y_0 : static axial load factor (0.5)

2.4.3 Safety Coefficient

The permissible static equivalent load is determined by the basic static load rating of the bearing. The operating limits of a bearing determined by the permanent deformation (local dent) described above depends on the bearing's performance requirements and operating conditions.

To estimate the degree of safety ensured for a basic static load rating, a safety coefficient is determined through experience.

$$f_s = \frac{C_0}{P_0} \quad \cdots\cdots (2.11)$$

where,

f_s : safety coefficient (See Table 2.5)
C_0 : basic static load rating, N
P_0 : static equivalent load, N

Table 2.5 Values of Safety Coefficient f_s

Operating Condition	f_s (Min.) Ball Bearing
High running accuracy required	2
Ordinary operating condition	1

Please contact JTEKT separately according to the applications.

3. Bearing Tolerances

The main factor to consider when selecting the bearing tolerances is application. Table 3.1 shows standards used to select the tolerances of miniature and extra-small ball bearings. Use this table as a reference when determining the required bearing tolerances.

The tolerance classes of miniature and extra-small ball bearings are specified in JIS B 1514 (Tolerances for Rolling Bearings) (JIS is based on ISO standards).

The tolerance classes for these bearings are as follows:

- Metric series miniature and extra-small ball bearings
  JIS Classes 0, 6, 5, 4, and 2

Table 3.2 shows the limits for chamfer dimensions and Tables 3.3 to 3.4 show bearing tolerances of miniature and extra-small ball bearings.

4. Rotation Speed Limit

The rotation speed of a bearing is restricted chiefly by temperature increases caused by frictional heat generated in the bearing. When the speed limit is reached, it becomes impossible to continue operation due to seizure and the like.

The limit on rotation speed of a bearing represents the maximum value at which the bearing can continue operation without generating seizure-causing heat.

Accordingly, the rotation speed limit differs with each bearing type, dimensions, and accuracy, as well as with lubrication methods, quality and quantity of lubricant, cage material and type, loading conditions, etc.

The rotation speed limit for grease lubrication or oil (oil bath) lubrication of each bearing is given in the dimension table. These values are applicable in cases where a bearing of a standard design is operated under normal loading conditions ($C/P \geqq 13$, $F_a/F_r \leqq$ approx. 0.25).

(C : basic dynamic load rating F_r : radial load
P : dynamic equivalent load F_a : axial load)

The classes and brands of some lubricants may not be suitable for high-speed operation even if they are excellent in other features. Consult JTEKT if the rotation speed of a bearing exceeds 80% of the catalog value.

4.1 Correction of the Rotation Speed Limit

Under some loading conditions, the rotation speed limit needs to be corrected by Equation (4.1). Such conditions include cases where $C/P < 13$ (namely, the dynamic equivalent load P is equal to or greater than approximately 8% of the basic dynamic load rating C), and in combined loading applications where the axial load exceeds 25% of the radial load.

$$n_a = f_1 \cdot f_2 \cdot n \quad \cdots\cdots (4.1)$$

where,

n_a : corrected rotation speed limit, min^{-1}

f_1 : correction coefficient determined from the load magnitude (See Fig. 4.1)

f_2 : correction coefficient determined from combined load (See Fig. 4.2)

n : rotation speed limit under normal load condition, min^{-1} (listed in the bearing dimension table)

C : basic dynamic load rating, N

P : dynamic equivalent load, N

F_r : radial load, N

F_a : axial load, N

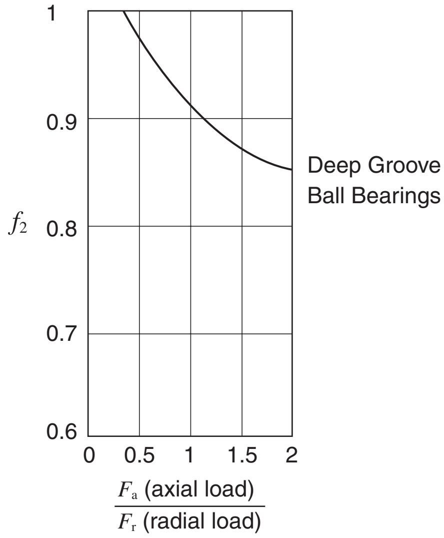

Fig. 4.2 Values of the Correction Coefficient f_2 Determined by Combined Load

4.2 Rotation Speed Limit for Sealed Miniature and Extra-Small Ball Bearings

The rotation speed limit for a miniature and extra-small ball bearing with contact seals is limited by the rubbing speed of the portion in contact with the seal. This allowable rubbing speed varies according to the rubber material of the seal. In JTEKT's miniature and extra-small ball bearing with standard type contact seals (nitrile rubber), 15 m/s is used.

The rotation speed limit for individual deep groove ball bearings with seals is given in the relevant bearing dimension table.

5. Bearing Fits

In general, light interference fits or slight clearance fits are used for miniature and extra-small ball bearings. Fits of considerable interference or clearance can be detrimental.

Selective fitting is recommended if it is possible to select shafts and housings with bearings classified according to bore and outside diameters. Selective fitting helps narrow down the range of fits so that bearing performance can be effectively improved.

In miniature and extra-small ball bearings, housings made of non-ferrous metal such as an aluminum alloy are frequently used. In applications with wide temperature ranges, the housings should be fitted with a steel liner. At low temperatures, the steel liner prevents housing shrinkage and at high temperatures, it minimizes expansion. Table 5.1 shows fits for tolerance miniature and extra-small ball bearings.

6. Bearing Internal Clearance

The internal clearance of a bearing refers to the amount of movement of the inner ring, while the outer ring remains stationary, or vice versa.

Movement in the radial direction reveals a radial internal clearance, while movement in the axial direction shows an axial internal clearance (see Fig. 6.1).

In measuring internal clearances of bearings, a specified measuring load is generally applied to obtain stable measurements. Accordingly, measurements taken this way are greater than the true clearance (known as the theoretical clearance) due to elastic deformation resulting from the measuring load.

In general, bearing internal clearances are specified in theoretical clearances.

The amount of internal clearance during operation (known as the running clearance) influences bearing performance characteristics, such as rolling life, heat generation, noise, and vibration.

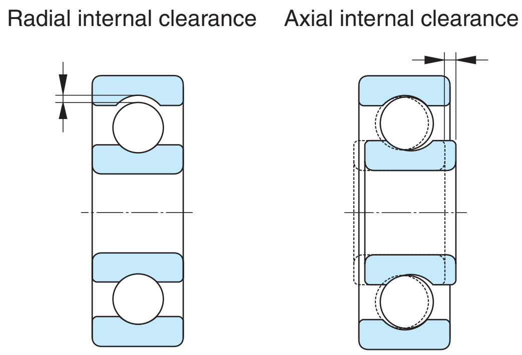

Fig. 6.1 Bearing Internal Clearance

Tables 6.1 and 6.2 show radial internal clearances and selection standards for miniature and extra-small ball bearings.

The axial internal clearance is dependant on the ball size, curvature of raceways, and radial internal clearance. If the radial internal clearance is constant, the axial internal clearance becomes greater as the ball size and raceway curvature increase.

Fig. 6.2 shows an example of the relationship between radial and axial internal clearance.

Application	Bearing Performance Requirements	Clearance Code	Radial Internal Clearance (μm)	Remark
Precision gear instruments **Servo mechanism** **Equipment used at low-speed**	1. Ensure narrow clearance without clearance adjustment in axial direction 2. Frictional torque is not taken into consideration 3. Neither durability nor rigidity for axial load is required	M1 M2	0 ~ 8	• Interference fit can not be used
Axial flow fans **Equipment used at low or medium speed and at normal temperatures**	1. Normal frictional torque is accepted for operation with axial load 2. Carry out clearance adjustment in axial direction 3. Ordinary durability and rigidity are required for axial load	M3 M4	5 ~ 13	• Interference fit can not be used in principle
Cleaners **Equipment used under high temperature and high-speed conditions**	1. Under axial load, frictional torque should be reduced 2. Carry out clearance adjustment in axial direction 3. High durability against radical changes in temperature 4. High durability and rigidity are required for axial load	M5 M6	13 ~ 28	1. Preloading by a spring is required 2. Interference fit may be used

7. Preload of Bearings

In general, bearings are used with the proper internal clearance during operation.

Some bearings for small motors are given a negative clearance by applying a preset axial load so as to minimize vibration. This way of using bearings is known as preloading.

7.1 Objective of Preload

- To improve the positioning accuracy in the radial and axial directions, and to improve the running accuracy, by minimizing runout
- To prevent bearing noise caused by vibration and resonance

7.2 Methods for Preloading

Preload is applied by fixed-position preloading or constant pressure preloading.

[Comparison between Fixed-position Preloading and Constant-pressure Preloading]

- Given the same preload force, fixed-position preloading produces smaller axial displacement. In other words, high rigidity is readily achieved by fixed-position preloading
- In constant-pressure preloading, springs absorb load variations and volume changes of the shaft caused by the temperature differentials between the shaft and housing. Hence the preload force varies little and is stable
- With fixed-position preloading a greater preload force can be realized

Consequently, fixed-position preloading is suitable when high rigidity is required. Constant-pressure preloading is appropriate for high-speed applications and the prevention of axial vibrations.

7.3 Preload Force

Preload can be applied to prevent noise caused by vibration. If, however, excessive preload is applied to a bearing, unusual heat, an increase in friction, and/or a reduction in fatigue life may result. Accordingly, the chosen preload force should fall within a range that produces no adverse effect.

In bearings for small motors, a wavy washer is generally used to apply light preload.

A guide to preload forces for miniature and extra-small ball bearings is shown in Table 7.1.

Table 7.1 Preload Forces for Miniature and Extra-Small Ball Bearings

Preload	Preload Force	Feature
Light preload	1.0% C	Axial rigidity not required Low torque is important
Medium preload	1.5% C	Both axial rigidity and low torque are required
Heavy preload	2.0% C	Axial rigidity is important Rather high torque is acceptable

C : basic dynamic load rating of bearing, kN

8. Bearing Lubrication

8.1 Objective of Lubrication and Methods

Lubrication is critical for bearings. The suitability of a lubricant and lubrication method greatly influences bearing life.

[Functions of Lubrication]

- Lubrication of each part of a bearing reduces friction and wear
- Removes heat generated in bearing by friction and other causes
- Extends bearing fatigue life by constantly forming an appropriate oil film between the rolling contact surfaces
- Provides rust prevention and dust proofing

Bearing lubrication methods take advantage of either grease or oil. Table 8.1 shows a general comparison of these methods.

Table 8.1 Comparison of Grease and Oil Lubrication

Item	Grease	Oil
Sealing device	Simple	Rather complicated (Care should be taken regarding maintenance)
Lubrication performance	Good	Excellent
Rotation speed	Low ~ medium speed	Suitable also for high speed applications
Replacement of lubricant	Rather cumbersome	Simple
Lubricant life	Relatively short	Long
Cooling effect	None	Good (circulation required)
Dust filtration	Difficult	Simple

8.2 Grease Lubrication

In general, shielded and sealed bearings have a suitable quantity of lubricating grease ready packed, so they can be used in their original condition.

Normally, the quantity of sealed grease is approximately 30% of inner space of the bearing. If more grease is applied, the bearing torque will increase which may lead to a leakage of grease or an increase in heat. Therefore, care should be exercised in this regard.

Grease life depends on its oxidation, thermal stability and the evaporation rate of the base oil. As bearing performance is greatly affected by the brand and type of grease used, consult JTEKT prior to selecting a grease.

Table 8.2 shows general-purpose lubricating greases used in miniature and extra-small ball bearings. Lubricating greases developed by JTEKT are shown in Table 8.3.

8.3 Oil Lubrication

Oil lubrication is superior to grease lubrication if it is necessary to reduce the starting or running torque to an extremely small value or if the load is very small and the rotation speed is high. Specifically, if a low torque is required in a low-speed application, bearings are run with a few drops of oil.

For high-temperature and high-speed applications, oil jet or oil mist lubrication is used. Oil mist lubrication is especially effective in high-speed applications.

JTEKT's standard lubricating oil is ASF12 (MIL-L-6085A)

8.4 Grease Life of Shielded and Sealed Miniature and Extra-Small Ball Bearings

Grease life of shielded and sealed miniature and extra-small ball bearings in which grease is sealed is estimated by the equation below:

$$\log L = 6.10 - 4.40 \times 10^{-6}\, d_{\mathrm{m}} n - 2.50\left(\frac{P_{\mathrm{r}}}{C_{\mathrm{r}}} - 0.05\right) - (0.021 - 1.80 \times 10^{-8} d_{\mathrm{m}} n)\, T \quad \cdots\cdots (8.1)$$

where,

L : grease life, h

d_{m} : $\dfrac{D+d}{2}$, mm

(D : bearing outside diameter, d : bearing bore diameter)

n : rotation speed, min^{-1}

P_{r} : equivalent radial load, N

C_{r} : basic dynamic load rating of bearing, N

T : bearing temperature, °C

To apply Equation (8.1), the conditions below must be met.

(1) Bearing temperature T °C

The equation is applicable when $T \leqq 120$

(If $T < 50$, assume that $T = 50$)

If $T > 120$, consult JTEKT.

(2) Rotation speed $d_{\mathrm{m}} n$

The equation is applicable when $d_{\mathrm{m}} n \leqq 500 \times 10^3$

(If $d_{\mathrm{m}} n < 125 \times 10^3$, use $d_{\mathrm{m}} n = 125 \times 10^3$)

If $d_{\mathrm{m}} n > 500 \times 10^3$, consult JTEKT.

(3) Load $\dfrac{P_{\mathrm{r}}}{C_{\mathrm{r}}}$

The equation is applicable when $\dfrac{P_{\mathrm{r}}}{C_{\mathrm{r}}} \leqq 0.2$

$\left(\text{If } \dfrac{P_{\mathrm{r}}}{C_{\mathrm{r}}} < 0.05, \text{ consider } \dfrac{P_{\mathrm{r}}}{C_{\mathrm{r}}} = 0.05\right)$

If $\dfrac{P_{\mathrm{r}}}{C_{\mathrm{r}}} > 0.2$, consult JTEKT.

9. Bearing Torque

There are some factors that have considerable influence on the frictional torque of bearings. Such factors include the cage sliding friction, rolling friction caused by load, and the viscous resistance of the lubricant.

It is possible to minimize the cage sliding friction and the rolling friction by means of an appropriate design and a tolerance finishing of the parts. Bearing torque fluctuates depending on slight variations and waviness in the raceway surfaces as these impair movements of the roiling elements.

The torque also varies according to the viscous resistance of the lubricant, which changes with rotation speed, the quality and quantity of lubricant, and temperature.

The frictional torque of a bearing is classified into starting torque and running torque.

The starting torque is that which is required to overcome the bearing's static friction. The starting torque varies depending on minor differences in tolerance of the raceway surfaces and rolling elements and the position of the rolling elements on the raceway surface immediately before the start.

The running torque refers to the frictional torque of a running bearing. Its magnitude changes with rotation speed, the quality and quantity of lubricant, and atmospheric temperature.

Typical data on running torque are shown in Figs. 9.1 to 9.3.

(1) Relationship between Rotation Speed and Running Torque

In general, running torque increases as rotation speed increases.

10. Bearing Materials

Most bearing rings and rolling elements of miniature and extra-small ball bearings are made of high carbon chrome bearing steel. Where bearings need to be corrosion resistant, martensite stainless steel is used.

Materials used for miniature and extra-small ball bearings and their properties are shown in Table 10.1. Chemical composition of materials used for bearing rings and rolling elements in miniature and extra-small ball bearings are shown in Table 10.2.

For cages and shields, materials such as carbon steel sheets, stainless steel sheets (JIS SUS300/400 series), phenol resin, and reinforced polyamide resin are used.

Resin products used for miniature and extra-small ball bearings and their respective operating temperature ranges are shown in Table 10.3.

Table 10.1 Materials Used for Miniature and Extra-Small Ball Bearings and Their Properties

[Note] 1) Actual operating temperature is limited by cage material, seal material, and lubricant.
Table 10.3 shows a guideline for operating temperature ranges in relation to resin cages.
If it is necessary to use a lubricant containing a specific additive, consult JTEKT.

11. Handling of Bearings

11.1 General Precautions for Handling

Since miniature and extra-small ball bearings are made to a higher tolerance than ordinary mechanical parts, one should accordingly handling them with due care.

1) Maintain bearings and their vicinity clean
2) Handle with care
   A severe shock to a bearing by rough handling may result in flaws, dents, fractures, and chipping.
3) Use the correct tools for handling
4) Exercise care for the prevention of rust
   Avoid handling them in a highly humid place. Wear gloves to prevent body oils from contacting the bearing surface.
5) Bearings should be handled by knowledgeable persons
6) Work standards for handling bearings should be formulated
   - Storage of bearings
   - Cleansing of bearings and surrounding parts
   - Inspection of dimensions and finish of parts
   - surrounding bearings
   - Mounting
   - Inspection after mounting
   - Maintenance inspection (regular inspection)

11.2 Storage of Bearings

Bearings are shipped after high-quality rust preventive oil is applied to them followed by suitable wrapping. Their quality is guaranteed as long as the wrapping is not damaged.

Bearings, if to be stored for an extended time, should be stored on a shelf at least 30 cm above the floor under conditions of 65% or less humidity at a temperature of around 20°C.
Avoid any place that allows direct exposure to the sun or contact with a cool wall.

11.3. Mounting Bearings

11.3.1 Precautions for Mounting

1) Preparation

Unwrap bearings just prior to mounting because they are wrapped to prevent rust.

The rust preventive oil applied to bearings offers good lubrication, so bearings for general use or grease-sealed bearings can be used immediately, without cleansing.

For measuring instruments and open type bearings for high-speed applications, remove preventive oil with clean washing oil. As rust is easily formed on bearings after they are cleansed, do not leave them unattended for long periods.

2) Inspection of Shaft and Housing

Clean the shaft and housing and verify that they are flawless and have no burrs caused by machining. The inside of the housing should be absolutely free from any residual lapping compound (SiC, Al_2O_3, etc.), molding sand, or chips.

Next, ensure that the shaft and housing are fabricated to the dimensions, shapes, and finish as specified on the design drawing.

Measure the shaft diameter and bore diameter of the housing at several positions as shown in Figs. 11.1 and 11.2. Additionally, carry out a thorough inspection of the shaft and housing fillet radius and shoulder squareness.

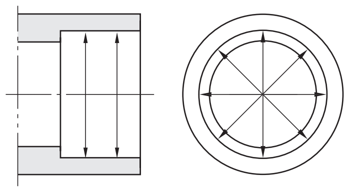

Fig. 11.2 Measuring Positions of Housing Bore Diameter

11.3.2 Mounting Bearings

Different methods are used to mount bearings depending on model and fitting conditions.
Since, in many cases, the inner ring rotates, an interference fit is used for the inner rings and a clearance fit is used for the outer rings. If the outer ring is to rotate, an interference fit is used for the outer rings.

Table 11.1 shows methods used to mount bearings with an interference fit.

11.4 Trial Run and Inspection

Trial run and inspection are carried out when bearings have been mounted, to check whether the mounting is appropriate.

In the case of small machines, the rotation condition is examined initially by manual operation. After confirmation that no fault exists as noted below, a further inspection is carried out by a powered run.

- Knocking ························ Possible causes are entry of foreign matter, flaw in rolling surfaces, etc.
- Excessive torque (heavy) ············ Possible causes are friction in the sealing device, insufficient clearance, mounting errors, etc.
- Uneven running torque ··············· Possible causes are defective mounting, mounting errors, etc.

Table 11.1 Press fit of bearings with cylindrical bores

Mounting methods	Description
 (a) Using press fit (the most widely used method)	• Whatever method is used, force should be applied to the bearing evenly. For that purpose, use a fixture and fit bearing gently. Do not apply a fixture to the outer ring for press-fitting of the inner ring, or vice versa.  (Inner ring press fit) (Outer ring press fit) (Inner ring press fit) • When both inner and outer rings of non-separable bearings require interference, use two kinds of fixtures as shown below and press-fit the bearing gently because rolling elements are likely to be damaged. Do not use a hammer in such cases.  (Simultaneous press fit of inner ring and outer ring)

11.5 Bearing Dismounting

Before dismounting bearings, consider their use after dismounting.

If bearings are to be disposed of, adopt as effortless a method as possible. Dismounting bearings for re-use or to identify causes of failure should be carried out with the same care as at time of mounting to avoid damage.

Specifically, bearings fitted with an interference are likely to be damaged during dismounting, how to dismount bearings should be taken into consideration at the design stage. It is recommended to design and make an appropriate jig for dismounting.

Marking the direction and position on the bearing is useful for identifying the causes of failure

[Dismounting Methods]

Table 11.2 shows common methods used for dismounting bearings for reuse or to investigate causes of failure, with interference fits.

Table 11.2 Dismounting of Cylindrical Bore Bearings

Inner Ring Dismounting Method	Description
 (a) Dismounting by press (b) Dismounting by jig	• When dismounting a non-separable bearing, no external force should be applied to the rolling elements • The simplest way is to draw out the bearing with a press as shown in Fig.(a). Provide a fixture to apply the force to the inner ring • The method illustrated in Fig. (b) uses a specific dismounting jig. Ensure that the claws of the jig catch the side face of the inner ring

12. Ceramic Bearings

Ceramics (silicon nitride) are suitable for making high-speed and light-weight bearings. Ceramic bearings have excellent features in that they are highly rigid, heat resistant, and highly corrosion resistant, as well as non-magnetic and non-conductive. Ceramic miniature and extra-small ball bearings are used in a wide range of advanced technological areas.

For details of ceramic bearings, refer to the JTEKT Extreme Special Environment Bearings (EXSEV bearings) Catalog, CAT. NO. B2004E.

■Extreme Special Environment Bearings (EXSEV bearings)

When bearings are used under high-temperature, vacuum and cleaning and required for special characteristics such as high-speed, light weight and small size, insulation, non-magnetic, they are considered as being used under special environments. EXSEV bearings are suitable for such environments. When bearings are to be used under special environments, contact JTEKT.

12.1 Properties of Ceramics

Table 12.1 shows a comparison between characteristics of ceramics and high carbon chrome bearing steel.

Table 12.1 Comparison between Characteristics of Ceramics (Si_3N_4) and High Carbon Chrome Bearing Steel (SUJ 2)

Item	Unit	Ceramics (Si_3N_4)	Bearing Steel (SUJ 2)	Features and Characteristics of Ceramics
Heat resistance	°C	800	180	Maintains high load capacity at high temperatures
Density	g/cm^3	3.2	7.8	Reduction in centrifugal force of rolling elements (balls and rollers) → Lengthened life and prevention of temperature increase
Coefficient of linear expansion	1/°C	3.2×10^{-6}	12.5×10^{-6}	Small changes in internal clearance caused by temperature increase → Prevention of vibrations, and small changes in preload force
Vickers' hardness	HV	1 500	750	
Modulus of longitudinal elasticity	GPa	320	208	Minor deformation in rolling contact zone → High rigidity
Poisson's ratio		0.29	0.3	
Corrosion resistance		Good	No good	Serviceable in special environments such as acid or alkali solutions
Magnetism		Non-magnetic material	Ferromagnetic material	Minor rotation fluctuations caused by magnetic forces in a strong magnetic field
Electrical conductivity		Insulant	Electrical conductor	Prevention of electric pitting
Bonding form of material		Covalent bond	Metallic bond	Less likely to generate adhesion (transfer) between rolling contacts if oil film diminishes

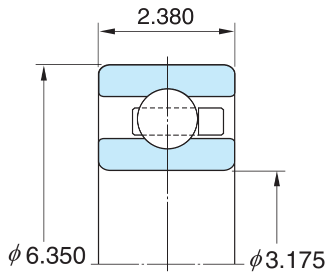
12.2 Features of Ceramic Bearings

12.2.1 High rotation speed

Ceramics are lighter than bearing steel. Accordingly, the centrifugal force and sliding caused by gyroscopic moments are reduced in rolling elements rotating at a high speed if they are made of ceramics.

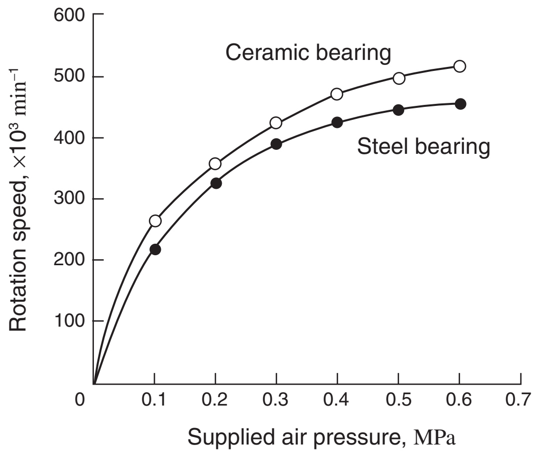
Consequently, ceramics are highly effective in controlling temperature increases.

[Test bearing]



Bearing	3NCOB74ST4M3
Ball	Ceramics (silicon nitride)
Inner and Outer Rings	Stainless steel
Cage (high-speed)	Heat-resistant reinforced polyimide resin

[Performance]



- Specification : Air turbine
- Ceramic bearings are capable of rotating at a 15% higher speed than steel bearings

12.2.2 Long Life (grease life)

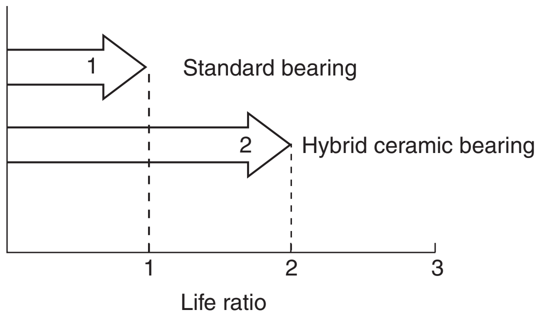
The service life of hybrid ceramic bearings is 2 times longer than that of steel bearings with grease lubrication.

(1) Grease lubrication example

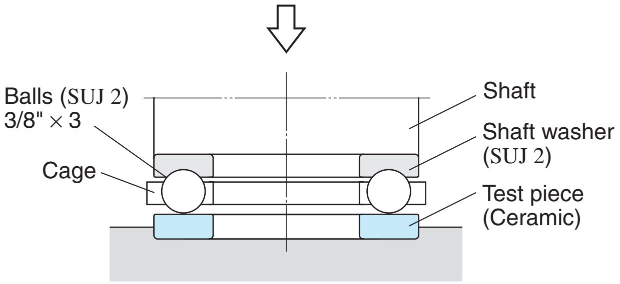
[Test bearing]

Bearing : 695
Rotation speed : 12 000 min^{-1}
Load : Preloading 14.7 N
Grease : SR grease (Grease fill is 25% of inner space)
Temperature : 70°C

[Life ratio of bearing]



(2) Oil lubrication example



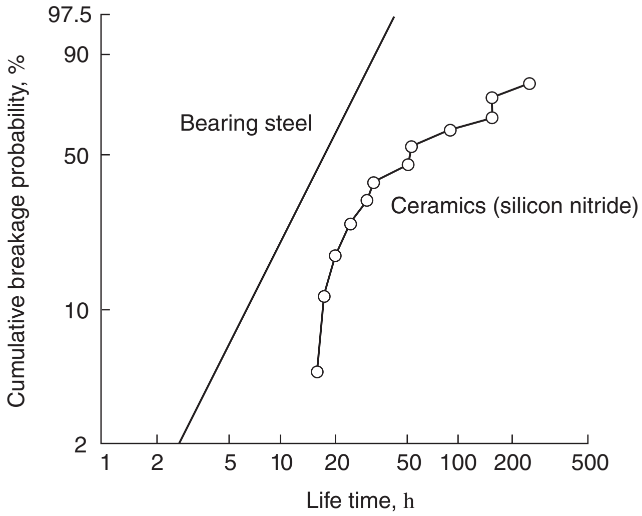
[Test method]

Test machine : Thrust Tester

Rotation speed : 1 400 min^{-1}

Load : Axial load 1 176N (per ball)

Lubricant : Turbine Oil (equivalent to ISO VG56)



12.2.3 Light Weight

The density of ceramics is approximately 40% of bearing steel. Therefore, ceramics are an ideal material for reducing the weight of bearings.

12.2.4 Small Dimensional Changes with Respect to Temperature

The coefficient of linear expansion of ceramics is small (25% of bearing steel).

12.2.5 High Rigidity

The hardness and the modulus of longitudinal elasticity are greater than that of bearing steel.

12.2.6 Insulation

Prevents electric pitting

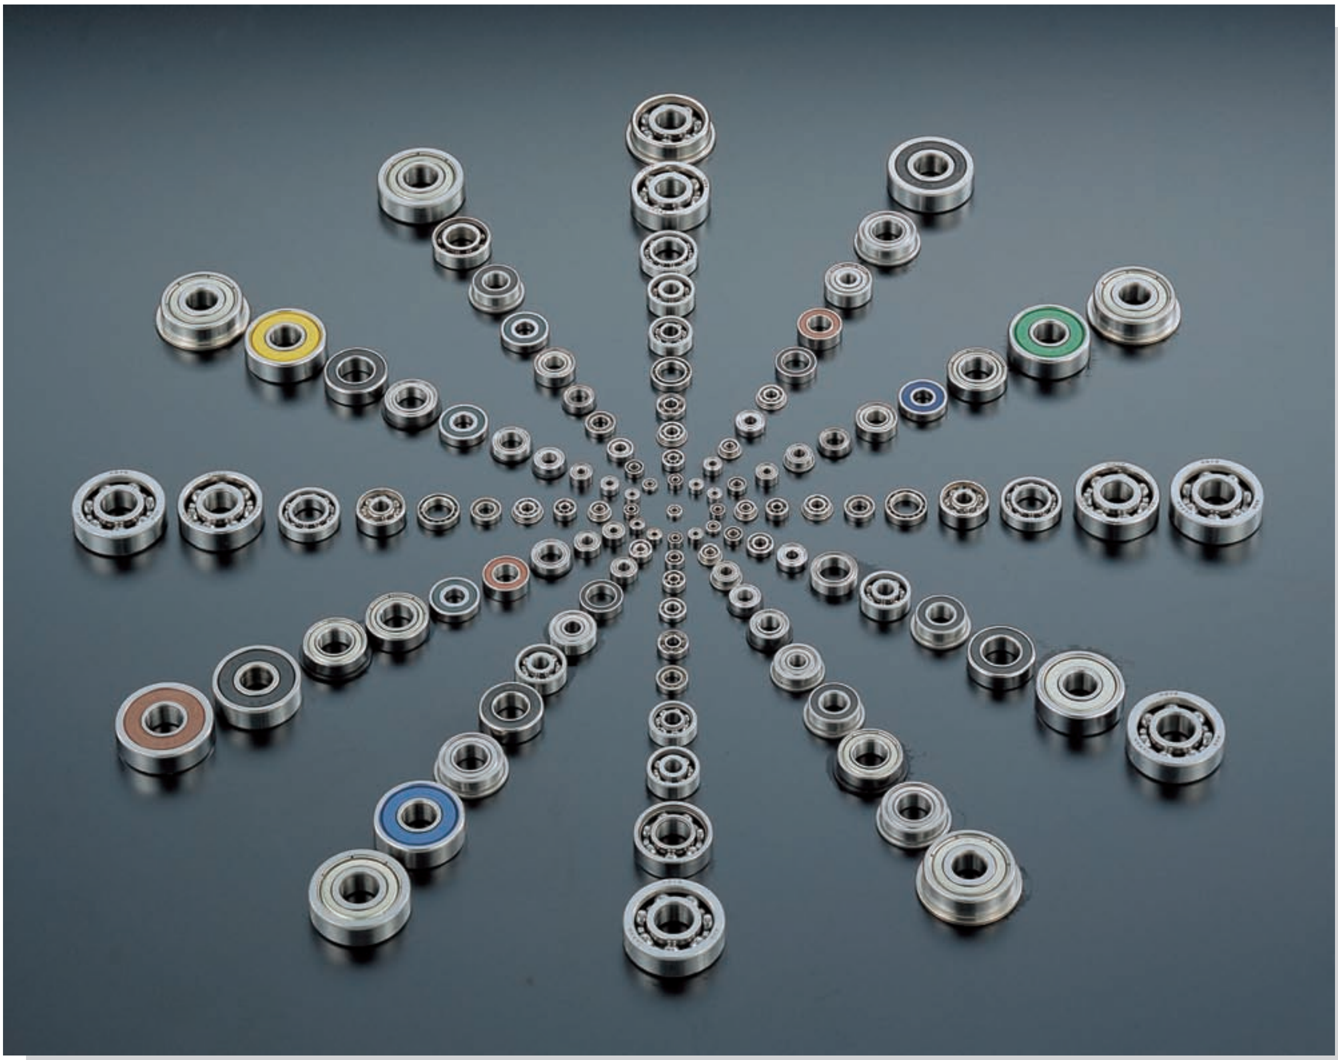
12.3 Application Examples of Ceramic Bearings

- Fan motors
- Turbochargers
- Spindle motors
- Dental hand pieces
- Polygon scanners
- Yarn twisting spindles
- Stepping motors
- Heat rollers
- Semiconductor production facilities
- Vacuum equipment
- Aero space development related equipment, etc.

13. Products Information

JTEKT is engaged in the manufacture and sales of all types of tolerance miniature and extra-small ball bearings such as open and sealed types as well as those with outer ring flange and locating snap ring.

Our recent developments, which include ceramic bearings, extreme special environment bearings (EXSEV bearings) and those with resin flanges, are used in a variety of applications.



• Miniature and Extra-Small Ball Bearings

• Ceramic Bearings

• Extreme Special Environment Bearings (EXSEV Bearings)

• Miniature and Extra-Small Ball Bearings with Resin Flanges (FN Bearings)

• Miniature and Extra-Small Ball Bearings with Resin Seals

• Miniature and Extra-Small Ball Bearings with Pulleys

We also produce a number of applied products such as bearings with resin or rubber pulleys.

For additional products, consult JTEKT.

• Miniature One-way Clutches
(Miniature one-way clutches with resin pulleys or resin gears are also available)

• Miniature Drawn Cup Needle Roller Bearings

• Miniature Linear Ball Bearings

[Note] 1) Numerical values in ( ) do not conform to JIS B 1521
2) The tolerance for D_2 is from +0.125/–0.050 mm. This does not apply to the portion formed by the molding gate.
3) The tolerance for C_2 is from 0/–0.050 mm.

Remark: 1. Consult JTEKT for flange dimensions and shapes which are not listed above.

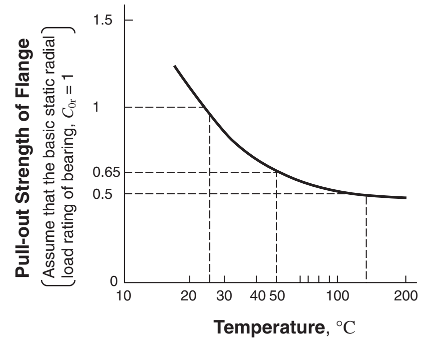
Performance

1. Application Conditions and Environment

Condition/Environment		Operating range
Resistance to axial load	< 50 °C	≦ 65% or less of C_{0r}
	≧ 50 °C	≦ 50% or less of C_{0r}
Heat resistance		max. 130 °C
Low temperature resistance		min. –30 °C
Moisture resistance		≦ 95% RH

Remark: C_{0r} denotes the basic static load rating of bearing

2. Pull-out Strength of Flange



[Note] These values for the pull-out strength of flange are valid when an axial load is applied evenly to the whole circumference of the flange. If the load is applied locally, the C_{0r} value may decrease by approximately 10% (C_{0r} denotes the basic static radial load rating of bearing).
